

ADELUS: A Performance-Portable Dense LU Solver for Distributed-Memory Hardware-Accelerated Systems

By

Vinh Dang, Joseph Kotulski, and Sivasankaran Rajamanickam

WACCPD@SC20 – Nov 13, 2020

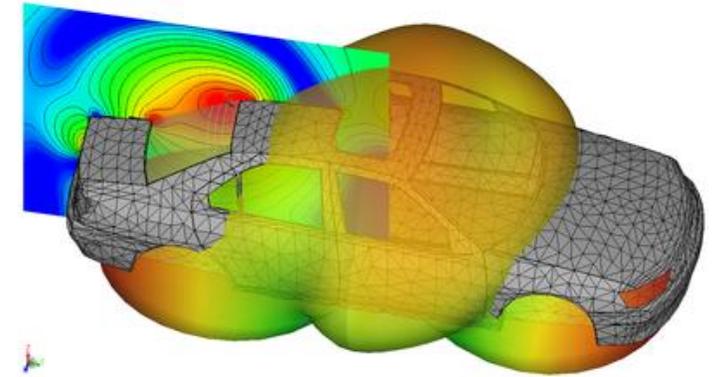

Sandia National Laboratories is a multi-mission laboratory managed and operated by National Technology & Engineering Solutions of Sandia, LLC, a wholly owned subsidiary of Honeywell International Inc., for the U.S. Department of Energy's National Nuclear Security Administration under contract DE-NA0003525.

SAND2020-12737 C

- Introduction
- Kokkos and Kokkos Kernels
- Method of Moments for Linear Electromagnetics
- Parallel LU Solver Implementation
 - Distributed, real/**complex, dense** matrices
 - ADELUS available in Trilinos
- Experimental Results
 - Achieve **7.7 PFLOPS** when integrated with a real-world application code
- Conclusions and Future Work

- ❑ Solving a dense linear equations system $\mathbf{A}*\mathbf{X}=\mathbf{B}$ is one of the most fundamental problems in numerous applications: physics, mathematics, and engineering
 - Our application of interest: boundary element method in electromagnetics (*method of moments*)
- ❑ Despite its high computational complexity, a direct solver (LU factorization) often provides more robust results than iterative solvers for extremely **ill-conditioned** system matrices
- ❑ A distributed-memory, dense LU solver capable of utilizing hardware accelerators available on top supercomputers is in need
- ❑ **Performance-portability** is important since future generation exa-scale HPC architectures are continuously evolving with significantly different architectures and programming models

ADELUS's Objectives

- ❑ A performance-portable dense LU solver for current and next generation distributed-memory hardware-accelerated HPC platforms
- ❑ Using LU factorization with partial pivoting for **double real/complex dense** linear systems in **distributed-memory** using MPI
- ❑ Using torus-wrap mapping scheme for workload distribution
- ❑ Leveraging **Kokkos** and **Kokkos Kernels** to provide performance portability
- ❑ Integrating with a **real-world application production code** and achieving PFLOPS performance

Kokkos and Kokkos Kernels

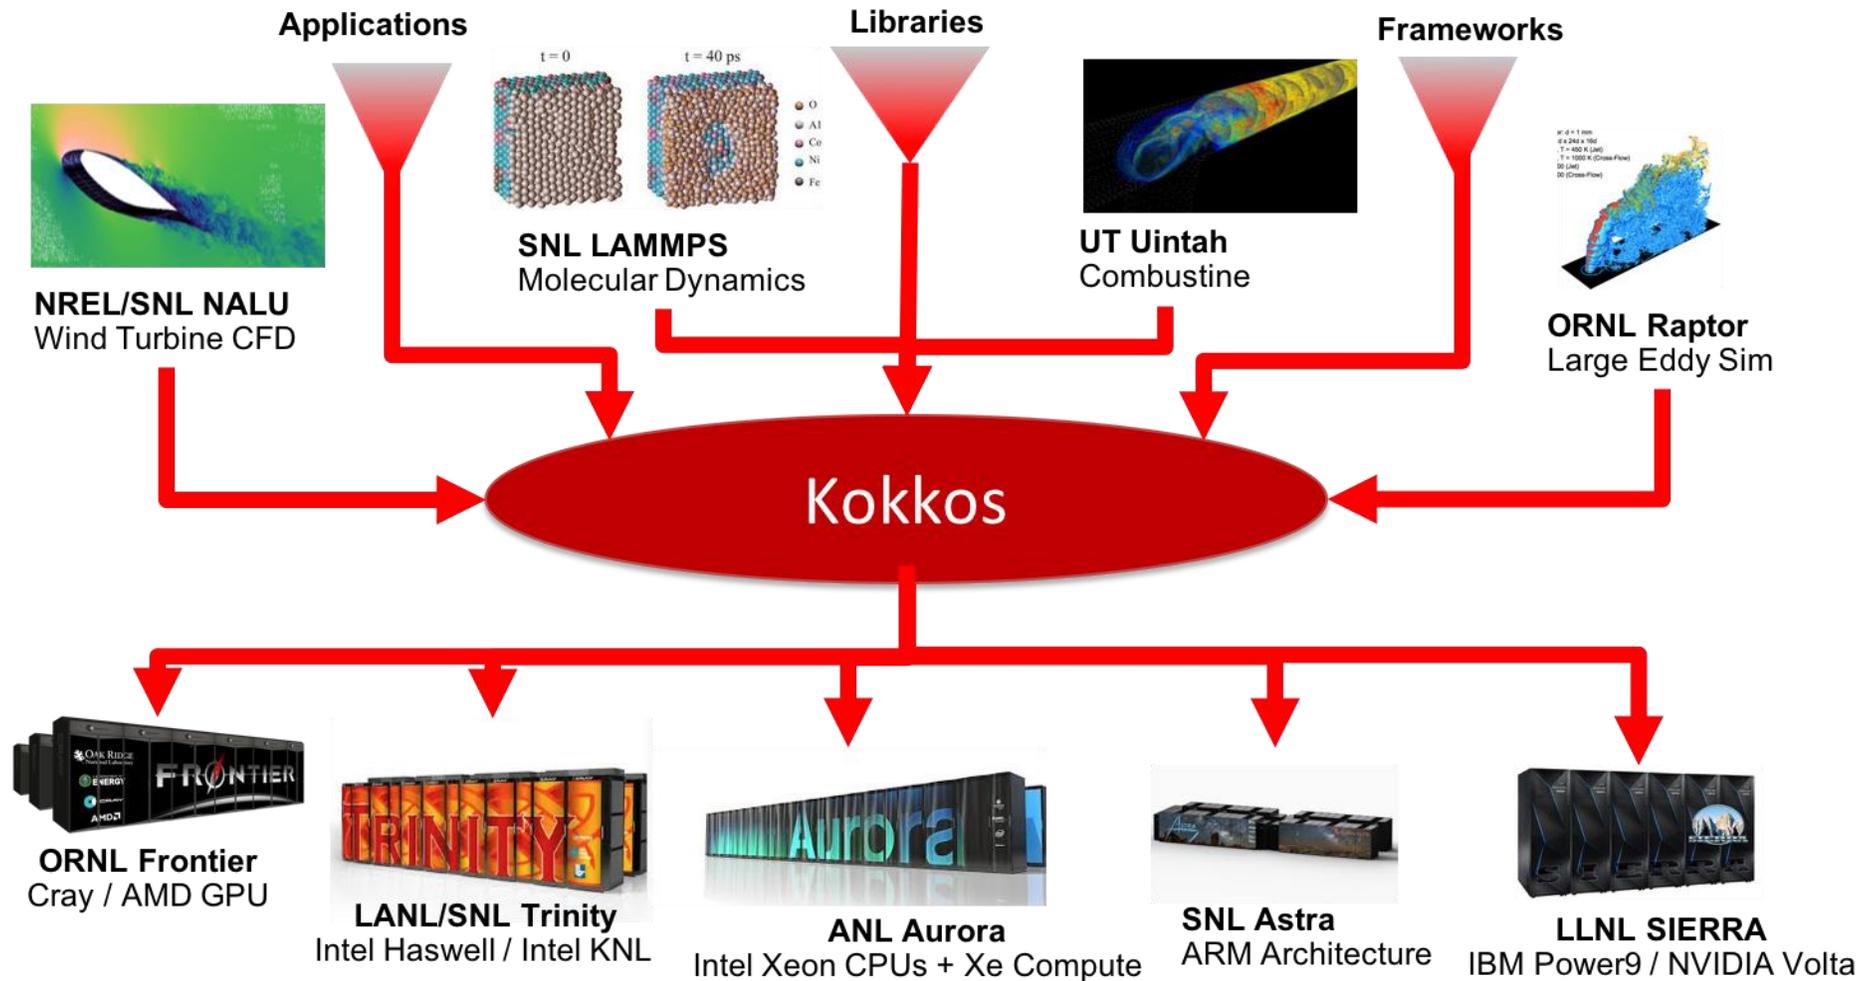

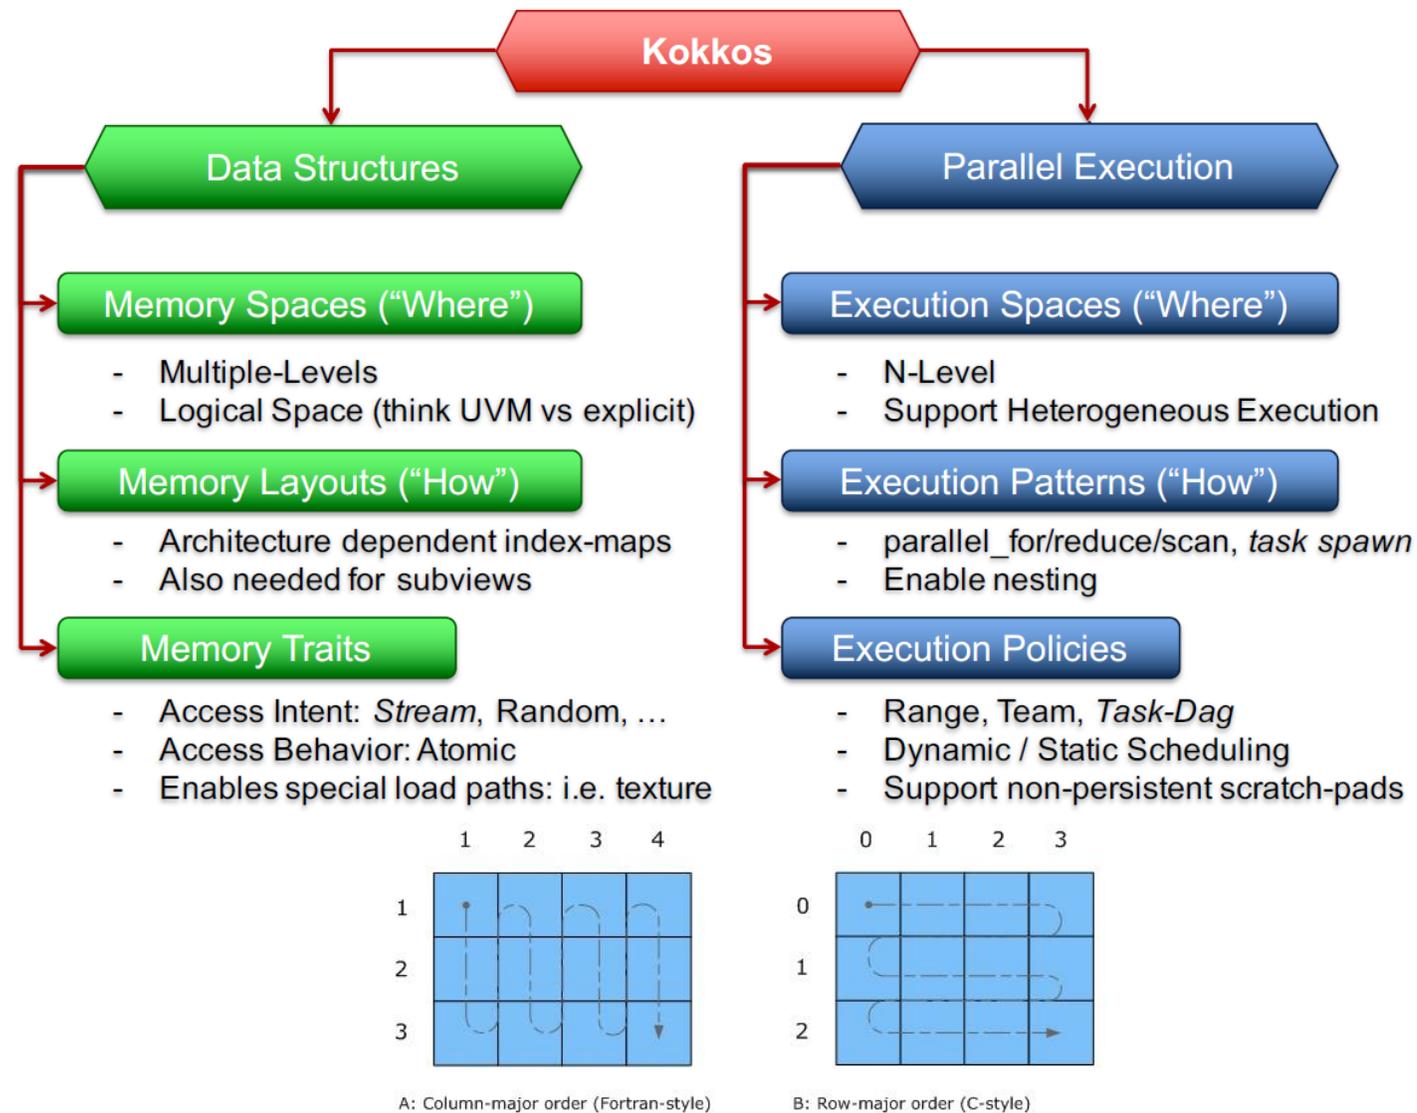

Kokkos is a **productive, portable, performant**, shared-memory programming model.

- ❑ is a C++ **library**, not a new language or language extension.
- ❑ supports **clear, concise, thread-scalable** parallel patterns.
- ❑ lets you write algorithms once and run on **many architectures**
 - e.g. OpenMP on multi-core CPUs, CUDA on NVIDIA GPUs, HIP for AMD GPUs, SYCL for Intel GPUs, ...
- ❑ **minimizes** the amount of **architecture-specific implementation details** users must know.
- ❑ **solves the data layout problem** by using multi-dimensional arrays with architecture-dependent **layouts**

An Abstraction Layer to Prevent Rewriting an Entire Code

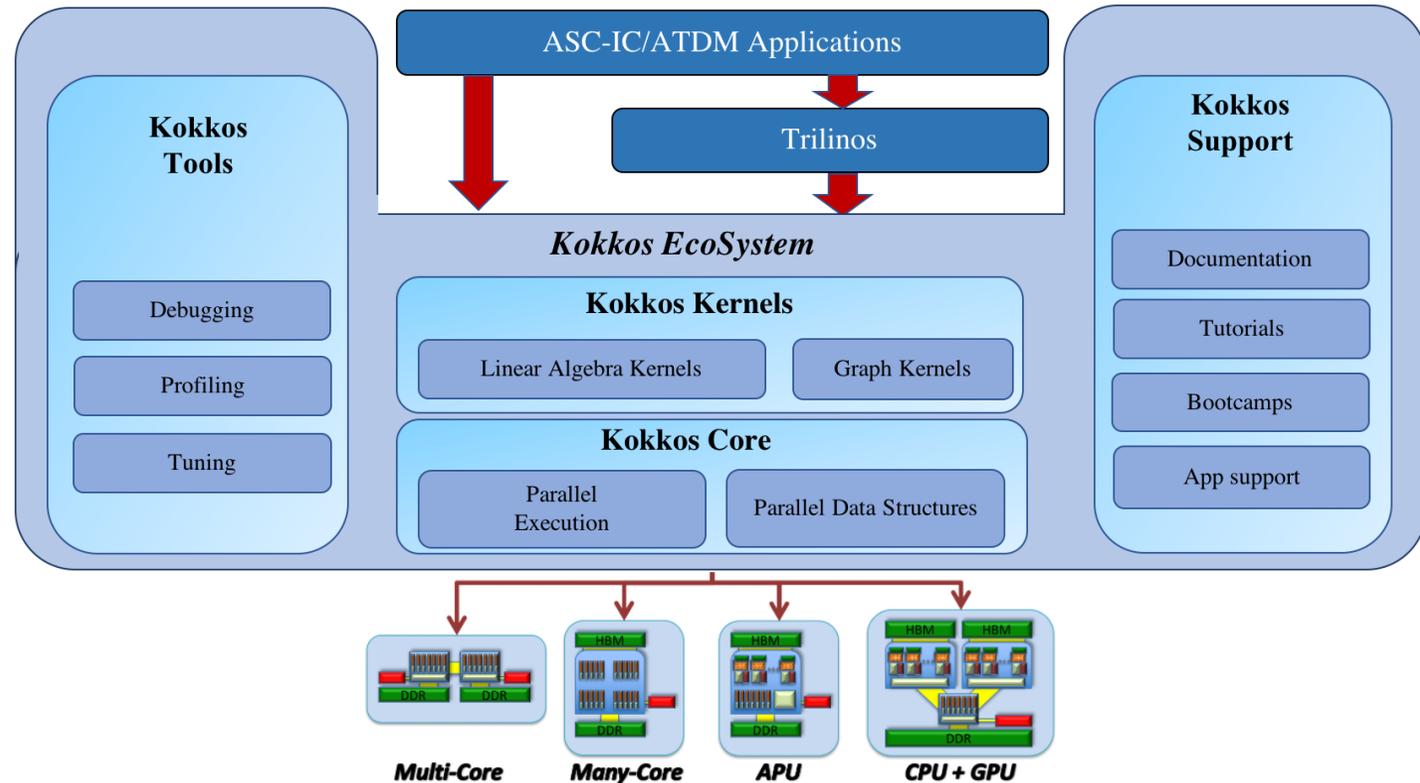

Kokkos Kernels

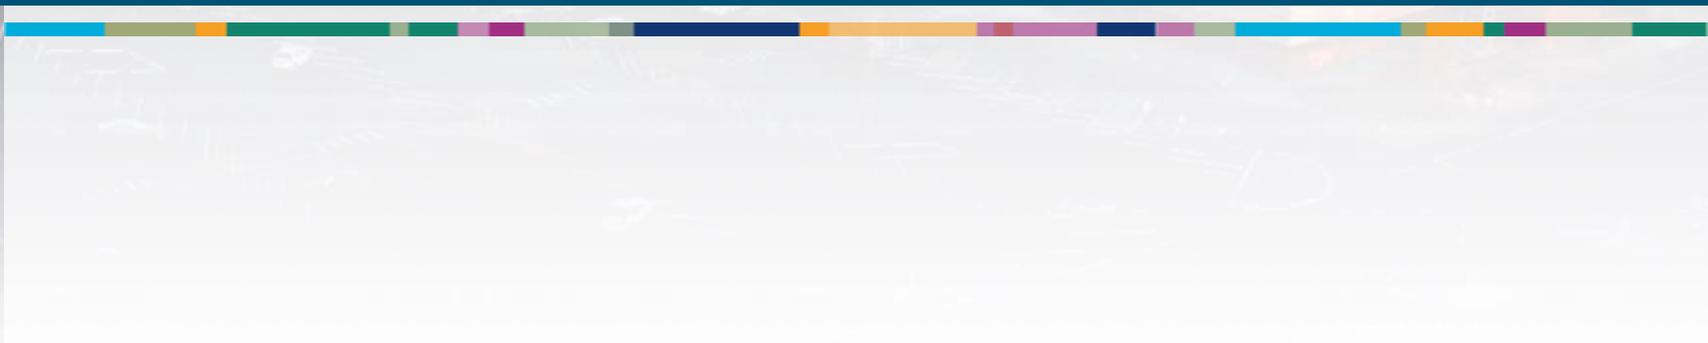

Kokkos Kernels is a library for *node-level*, performance-portable, computational kernels for sparse/dense linear algebra and graph operations, using the Kokkos.

- ❑ KK is available publicly both as part of Trilinos and as part of the **Kokkos ecosystem** (<https://github.com/kokkos/kokkos-kernels>)
- ❑ **Building block** of a solver, linear algebra library that uses MPI and threads for parallelism, or it can be used stand-alone in an application.
- ❑ Generic implementations for various scalar types and data layouts
- ❑ Interfaces to **vendor-provided kernels** available in order to leverage their high-performance libraries
- ❑ Several new kernels are being added as needed by the applications

Method of Moments for Linear Electromagnetics

Maxwell's Equations in the Frequency Domain

Maxwell's Equations:

$$\text{Faraday : } \nabla \times \mathbf{E} = -j\omega\mathbf{B}$$

$$\text{Ampere - Maxwell : } \nabla \times \mathbf{H} = \mathbf{J} + j\omega\mathbf{D}$$

$$\text{Electric Gauss : } \nabla \cdot \mathbf{D} = \rho$$

$$\text{Magnetic Gauss : } \nabla \cdot \mathbf{B} = 0$$

Vector and Scalar Potentials:

$$\mathbf{E} = -j\omega\mathbf{A} - \nabla\Phi$$

$$\mathbf{B} = \nabla \times \mathbf{A}$$

Lorenz gauge condition:

$$\nabla \cdot \mathbf{A} = -j\omega\epsilon\mu\Phi$$

Wave Equations:

$$\nabla^2 \mathbf{A} + \omega^2 \mu \epsilon \mathbf{A} = -\mu \mathbf{J}$$

$$\nabla^2 \Phi + \omega^2 \mu \epsilon \Phi = \rho / \epsilon$$

Instead of solving Maxwell's equations in 3D space via the wave equations, we solve them on the boundary between regions.

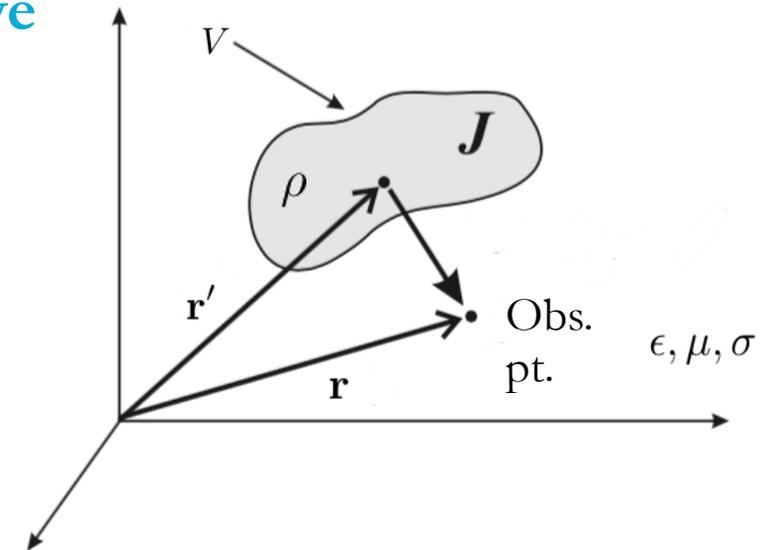

For a linear homogeneous, unbounded medium:

$$\mathbf{A} = \int_V \mu \mathbf{J}(\mathbf{r}') g(\mathbf{r}|\mathbf{r}') dv'$$

$$\Phi = - \int_V \frac{\rho(\mathbf{r}')}{\epsilon} g(\mathbf{r}|\mathbf{r}') dv'$$

Free-Space Green's Function:

$$g(\mathbf{r}|\mathbf{r}') = \frac{e^{-jk|\mathbf{r}-\mathbf{r}'|}}{4\pi|\mathbf{r}-\mathbf{r}'|}$$

Integral Equations (Boundary Element Method – BEM)

Example of an electric field integral equation (EFIE) for metallic scatterer:

Through the equivalence principle, we consider the **current on the object boundary** instead of the field around and inside the object. Enforcing the boundary condition at the surface:

$$\hat{\mathbf{n}} \times (\mathbf{E}_{\text{inc}} + \mathbf{E}_{\text{scat}}) = \mathbf{0}$$

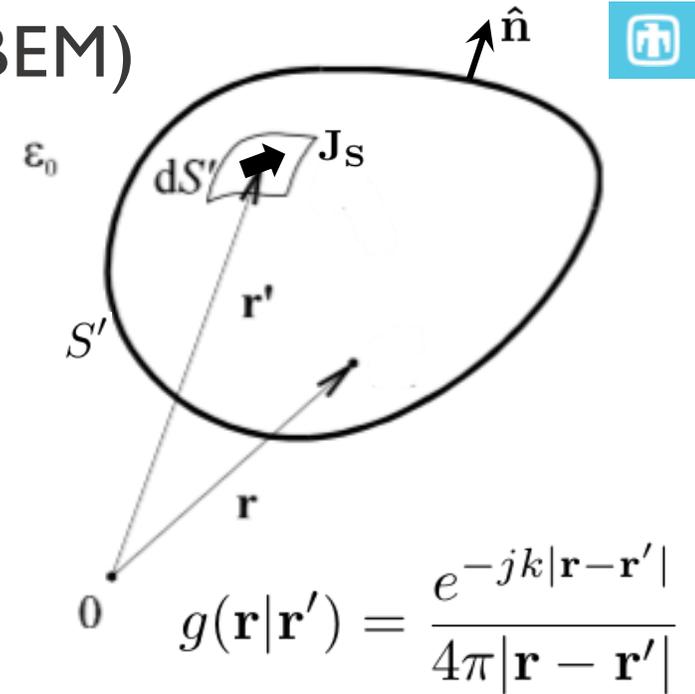

where,

$$\mathbf{E}_{\text{scat}} = -j\omega\mu \int_{S'} \left(\underbrace{\mathbf{J}_{\mathbf{S}}(\mathbf{r}')g(\mathbf{r}|\mathbf{r}')}_{\text{Vector Potential}} + \underbrace{\frac{1}{\omega^2\mu\epsilon} \nabla' \cdot \mathbf{J}_{\mathbf{S}}(\mathbf{r}') \nabla g(\mathbf{r}|\mathbf{r}')}_{\text{Scalar Potentials}} \right) ds'$$

results in the following integral equation:

$$\int_{S'} \hat{\mathbf{n}} \times \left(\mathbf{J}_{\mathbf{S}}(\mathbf{r}')g(\mathbf{r}|\mathbf{r}') + \frac{1}{\omega^2\mu\epsilon} \nabla' \cdot \mathbf{J}_{\mathbf{S}}(\mathbf{r}') \nabla g(\mathbf{r}|\mathbf{r}') \right) ds' = \frac{1}{j\omega\mu} \hat{\mathbf{n}} \times \mathbf{E}_{\text{inc}}$$

$$L \{ \mathbf{J}_{\mathbf{S}} \} = \frac{1}{j\omega\mu} \hat{\mathbf{n}} \times \mathbf{E}_{\text{inc}}$$

Method of Moments (MoM)

Numerical solution of integral equation:

$$L\{\mathbf{J}_S\} = \frac{1}{j\omega\mu} \hat{\mathbf{n}} \times \mathbf{E}_{\text{inc}}$$

Expand unknown in a set of basis functions:

$$\mathbf{J}_S(\mathbf{r}) \approx \sum_n I_n \mathbf{f}_n(\mathbf{r})$$

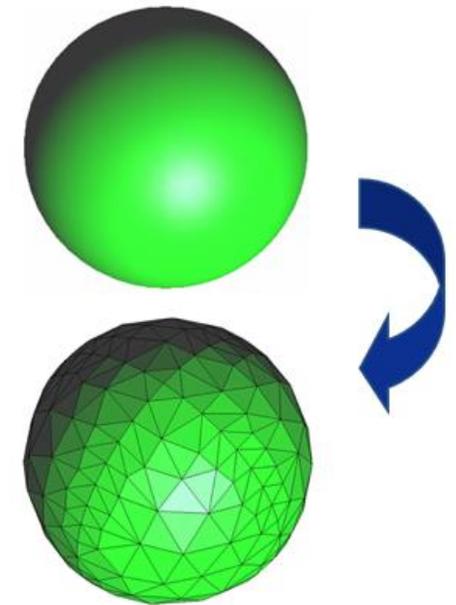

Test integral equation with basis functions.

$$\int_S \mathbf{f}_m \cdot L\{\mathbf{J}_S\} ds = \frac{1}{j\omega\mu} \int_S \mathbf{f}_m \cdot (\hat{\mathbf{n}} \times \mathbf{E}_{\text{inc}}) ds$$

$$\bar{\mathbf{Z}}\mathbf{I} = \mathbf{V}$$

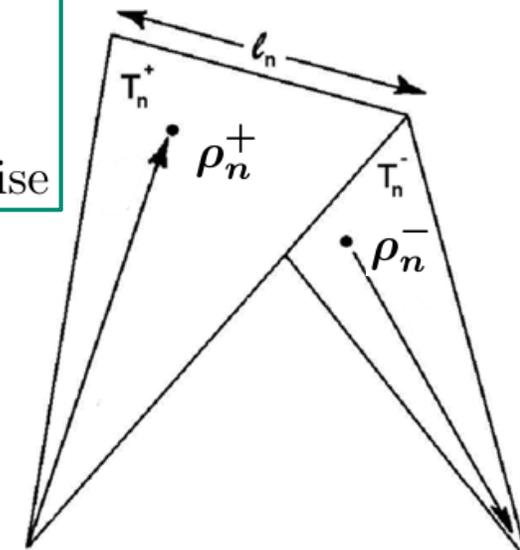

$$Z_{m,n} = \int_{f_m} \int_{f_n} \left[j\omega\mu \mathbf{f}_m \cdot \mathbf{f}_n - \frac{j}{\omega\epsilon} \nabla \cdot \mathbf{f}_m \nabla' \cdot \mathbf{f}_n \right] \frac{e^{-ikr}}{4\pi r}$$

Discretize the scatterers

$$\mathbf{f}_n(\mathbf{r}) = \begin{cases} \frac{\ell_n}{2A_n^+} \rho_n^+ & \mathbf{r} \in T_n^+ \\ \frac{\ell_n}{2A_n^-} \rho_n^- & \mathbf{r} \in T_n^- \\ \mathbf{0} & \text{otherwise} \end{cases}$$

Dense, Complex Matrix

Divergence-conforming Rao-Wilton-Glisson (RWG) basis functions

Parallel LU Solver Implementation

ADELUS Interface and Storage

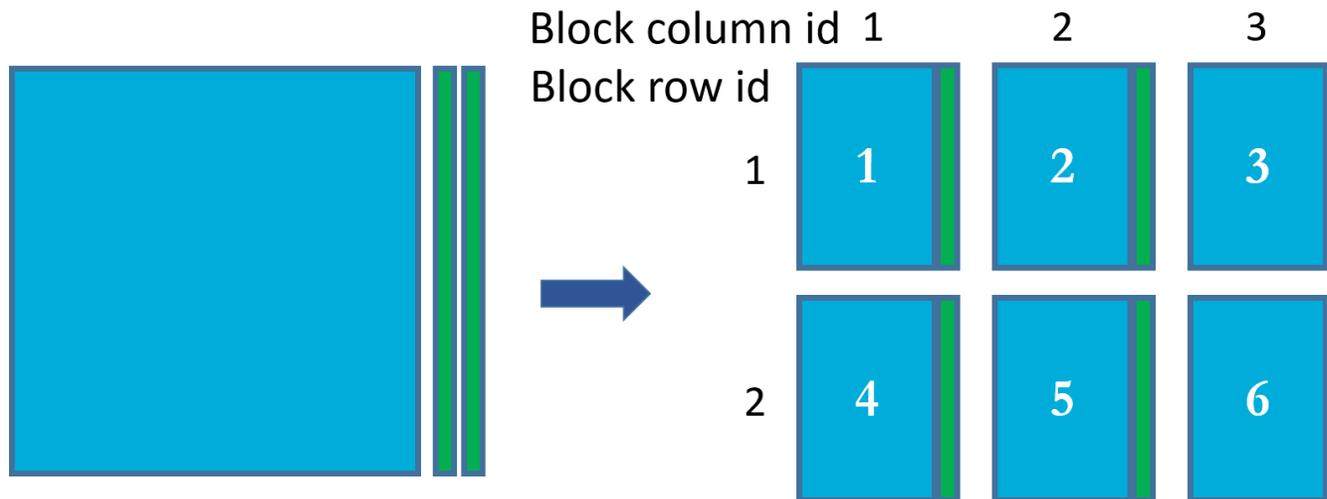

- Dense matrix and RHS vectors that are **block-mapped** to the MPI processes
- ADELUS is called by MPI processes with the matrix portions packed with RHS vectors (column-major order) as their inputs
- ADELUS data container is implemented by the **Kokkos View** for portability

In the host memory:

```
Kokkos::View<Kokkos::complex<double>**, Kokkos::LayoutLeft, Kokkos::HostSpace>
A("A", my_rows, my_cols+my_rhs);
```

In the CUDA device memory:

```
Kokkos::View<Kokkos::complex<double>**, Kokkos::LayoutLeft, Kokkos::CudaSpace>
A("A", my_rows, my_cols+my_rhs);
```

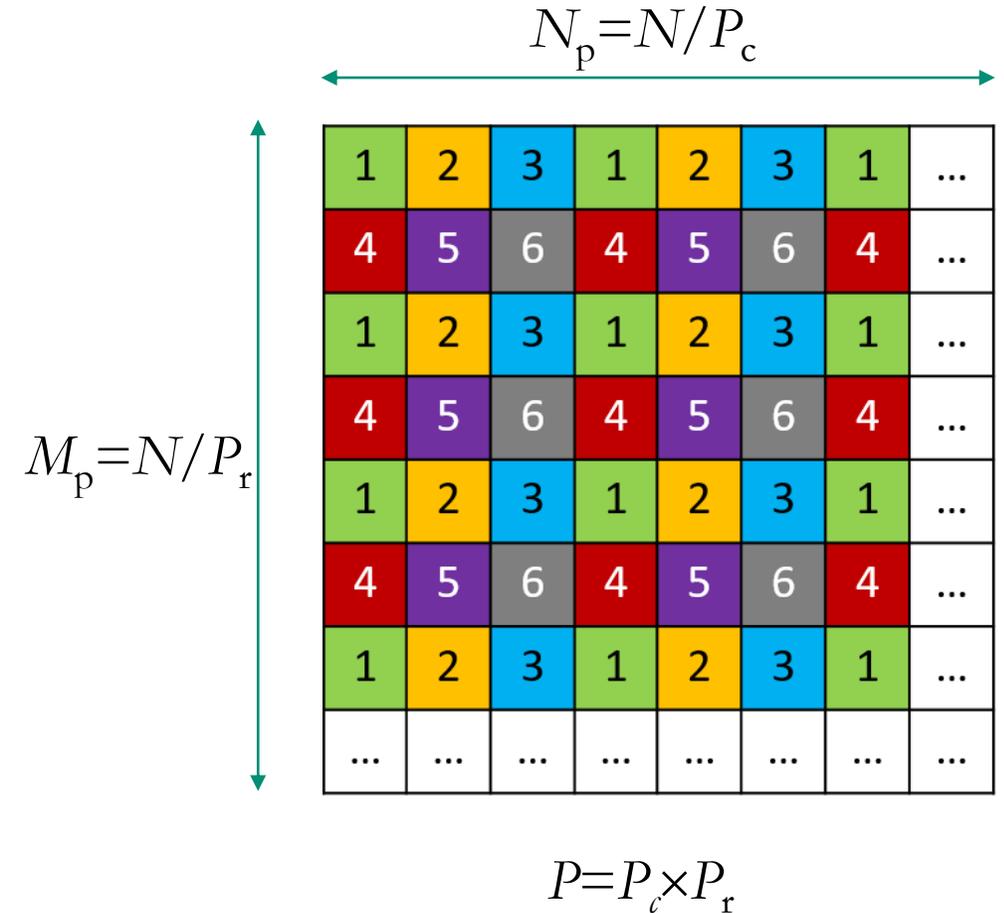

- Total number of MPI processes = 6
- Number of processes for a row = 3
- Number of right-hand sides = 2

Torus-Wrap Mapping

- Advantage: each process has nearly the same workload and the process idle time is minimized
- Column indices assigned to a MPI process constitute a linear sequence with step size P_c
- Row indices are in a sequence separated by P_r
- No need to redistribute the block-mapped matrix for torus-wrapped solver
 - A block-mapped system can be solved by a solver assuming a torus-wrapped system.
- Solution vectors are corrected afterwards by straightforward **permutations**

- Total number of MPI processes: 6 ($P=6$)
- Number of processes for a row: 3 ($P_c=3$)
- Number of right-hand sides: 2

LU Factorization and Forward Solve

- ❑ *Right-looking variant* of the LU factorization with *partial pivoting*
- ❑ Kokkos Kernels BLAS interfaces are used for local matrices in each MPI process
 - Calls to optimized vendor library BLAS routines: multi-threaded CPU (IBM's ESSL BLAS), massively parallel GPU architectures (cuBLAS)
- ❑ CUDA-aware MPI: simple communication patterns: point-to-point communication and collective communication
- ❑ 4 basic steps per iteration:
 1. Find the pivot: each process **finds** its own local maximum entry in the current column and then **exchanges** for the global pivot value.
 2. Scale the current column with the pivot value, and generate and **communicate** column update vector from the current column
 3. **Exchange** pivot row and diagonal row
 4. Update the current column, and when saving enough columns, update Z via **GEMM**

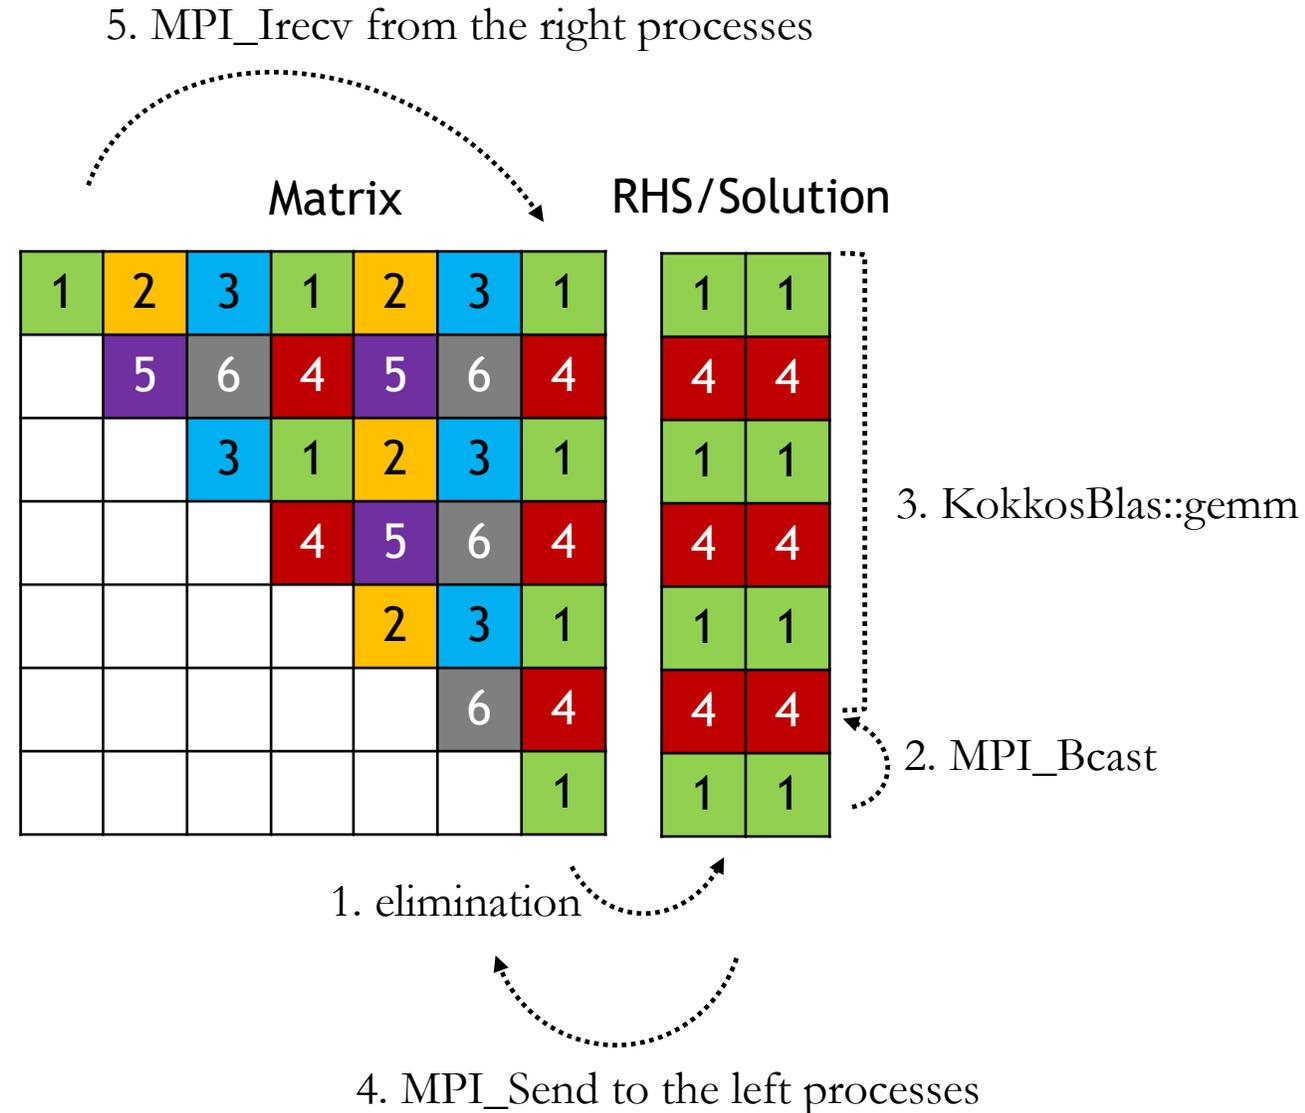

```
KokkosBlas::iamax()  
KokkosBlas::scal()  
KokkosBlas::copy()  
KokkosBlas::gemm()
```

```
MPI_Send()  
MPI_Recv()  
MPI_Irecv()  
MPI_Allreduce()  
MPI_Bcast()
```

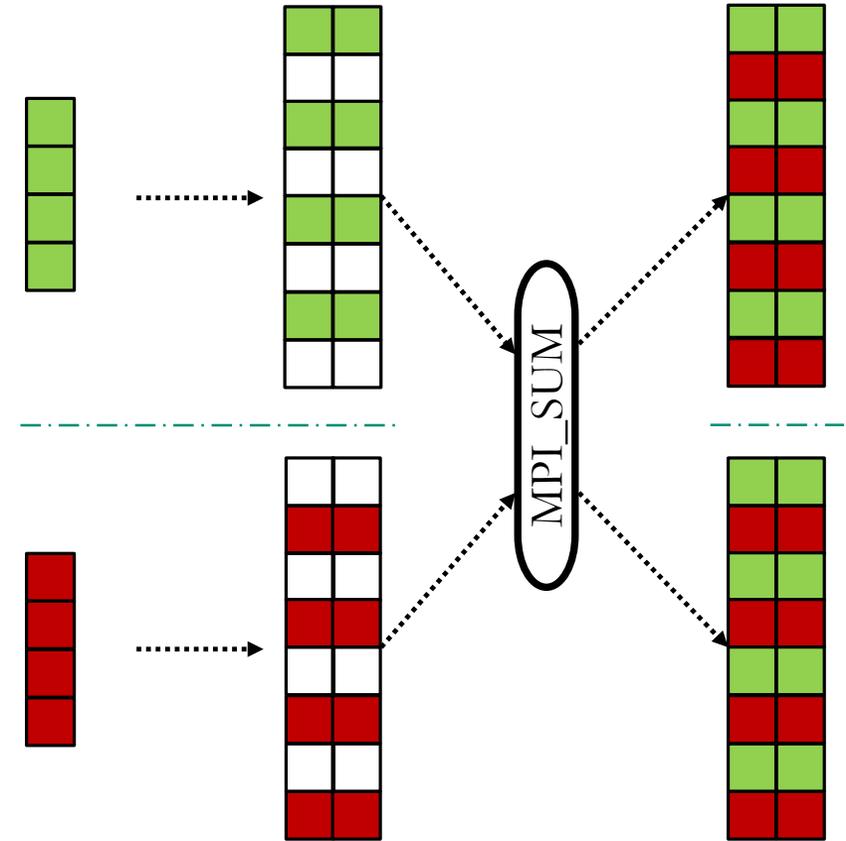

□ Backward Solve

1. The **elimination** of the RHS/Solution is performed by the process owning the current column using the **Kokkos parallel_for** across the RHS/Solution vectors
2. The results from the elimination step are **broadcasted** to all the processes within the MPI column sub-communicator
3. The **KokkosBlas::gemm** is then called to update the RHS/Solution
4. **Send** the RHS/Solution vectors are sent to the left processes
5. **Receive** the RHS/Solution vectors from the right processes

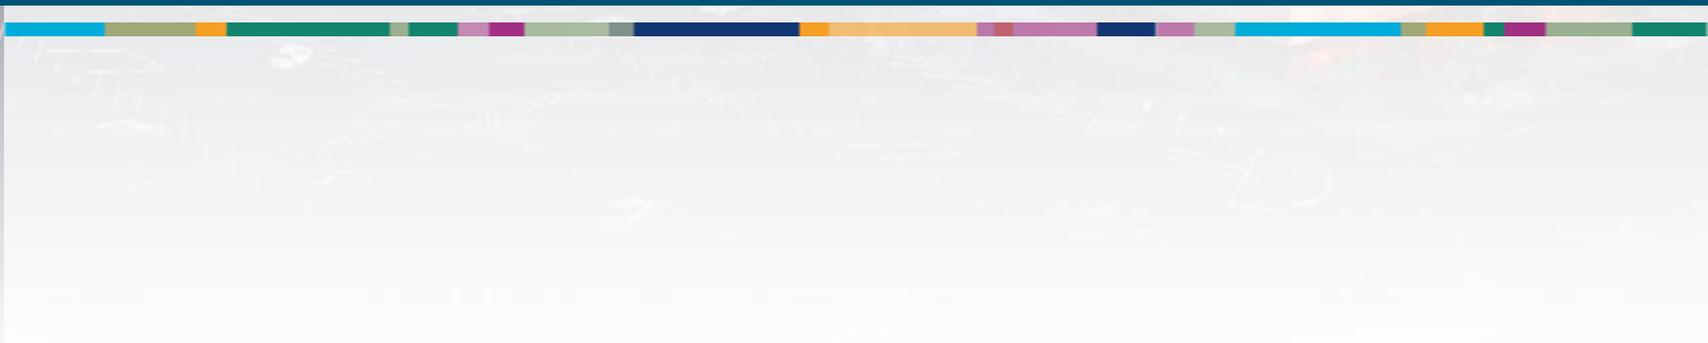

- Permutation: to “unwrap the results”
 - Solver assumes the torus-wrap mapping scheme while the input matrix is not torus-wrapped
 - A temporary buffer for global solution vectors created
 - Kokkos `parallel_for` to fill the correct locations in the global vectors
 - `MPI_Allreduce` to collectively update the change

Experimental Results

□ **Summit** system at the ORNL (4608 nodes): evaluating performance of ADELUS with **randomly-generated matrices**

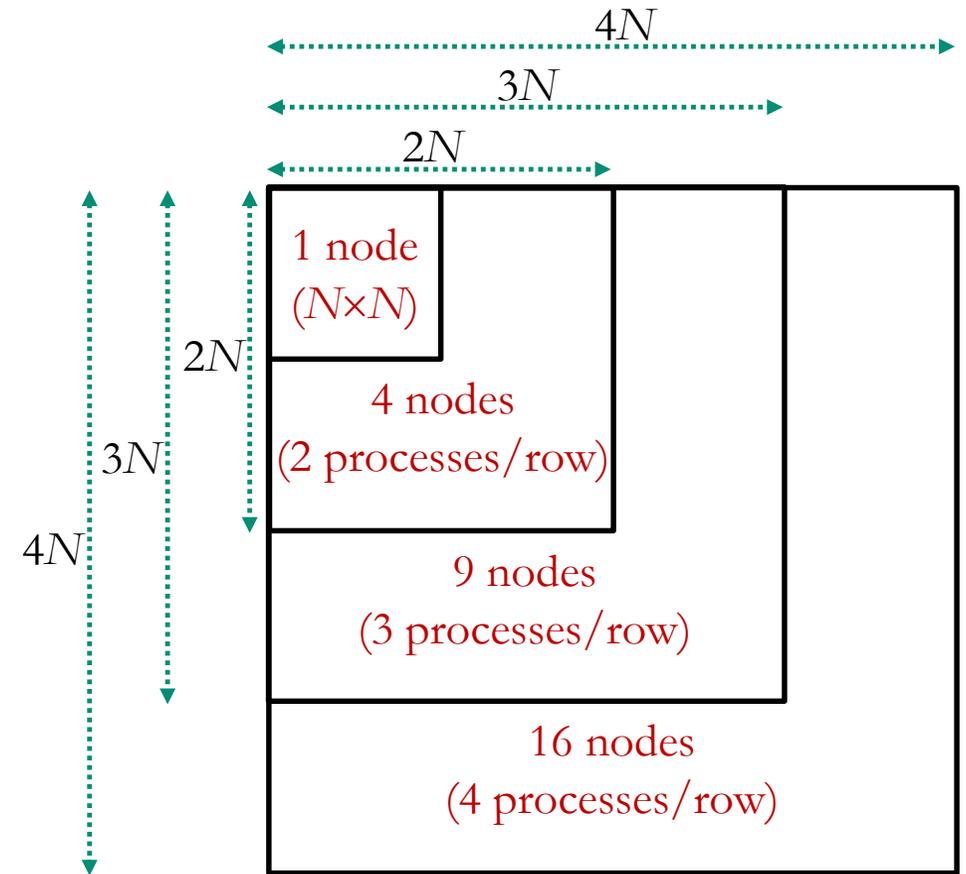

- Hardware (per node): 2 POWER9 CPUs (22 cores/each), **6** V100 GPUs (16GB memory/GPU)
 - Intra-node connection: NVIDIA's NVLink 2.0
 - Inter-node connection: Mellanox dual-rail enhanced data rate (EDR) InfiniBand network
- Software environment: **GCC 7.4.0**, CUDA 10.1.243, ESSL 6.2.0, **Spectrum MPI 10.3.1**
- DPLASMA: IBM XL C/C++ Compiler 16.1.1 instead of GCC 7.4.0
- SLATE: we use GCC 6.4.0 and ESSL 6.1.0, Netlib SCALAPACK 2.0.2

□ **Sierra** system at the LLNL (4320 nodes): demonstrating performance of ADELUS when integrated into a **production electromagnetic application code, EIGER**

- Hardware (per node): 2 POWER9 CPUs (22 cores/each), **4** V100 GPUs (16GB memory/GPU)
 - Intra-node connection: NVIDIA's NVLink 2.0
 - Inter-node connection: Mellanox dual-rail enhanced data rate (EDR) InfiniBand network
- Software environment: **GCC 7.2.1**, CUDA 10.1.243, ESSL 6.2.0, **Spectrum MPI 10.3.0**

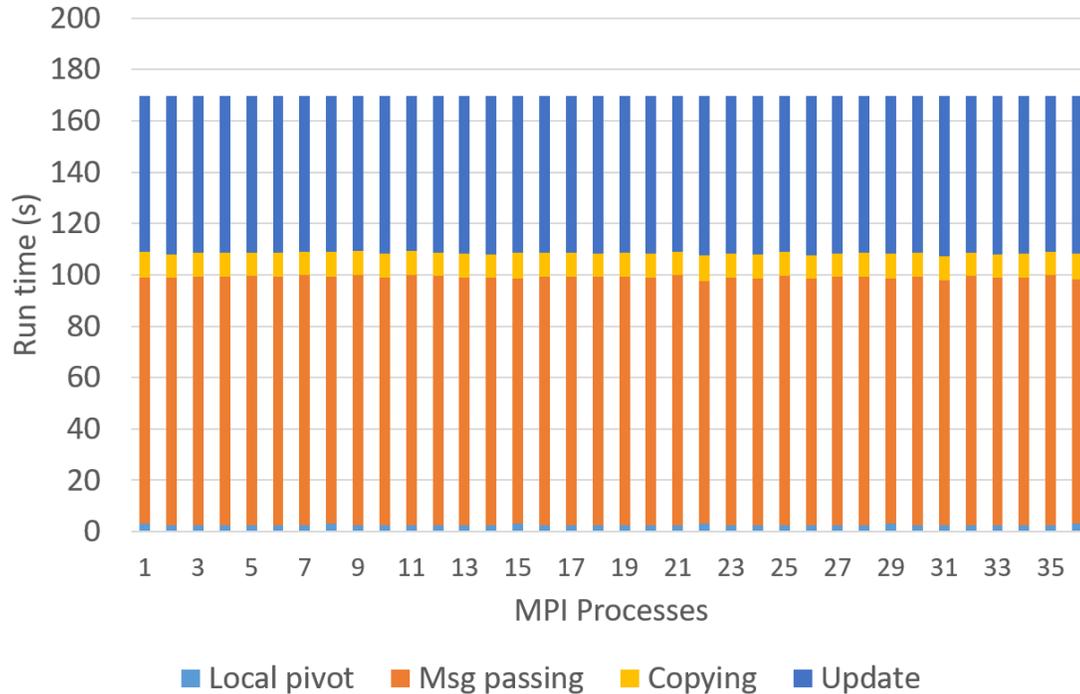

Randomly-Generated Matrices

- ❑ Single RHS vector and the matrix size is increased as we increase the hardware resource
- ❑ GPU backend: ADELUS runs with one MPI rank per GPU.
- ❑ CPU backend: ADELUS runs with one MPI rank per node (42 cores)
- ❑ Baseline: a matrix ($N \times N$) represented in double complex precision occupied a single GPU's memory

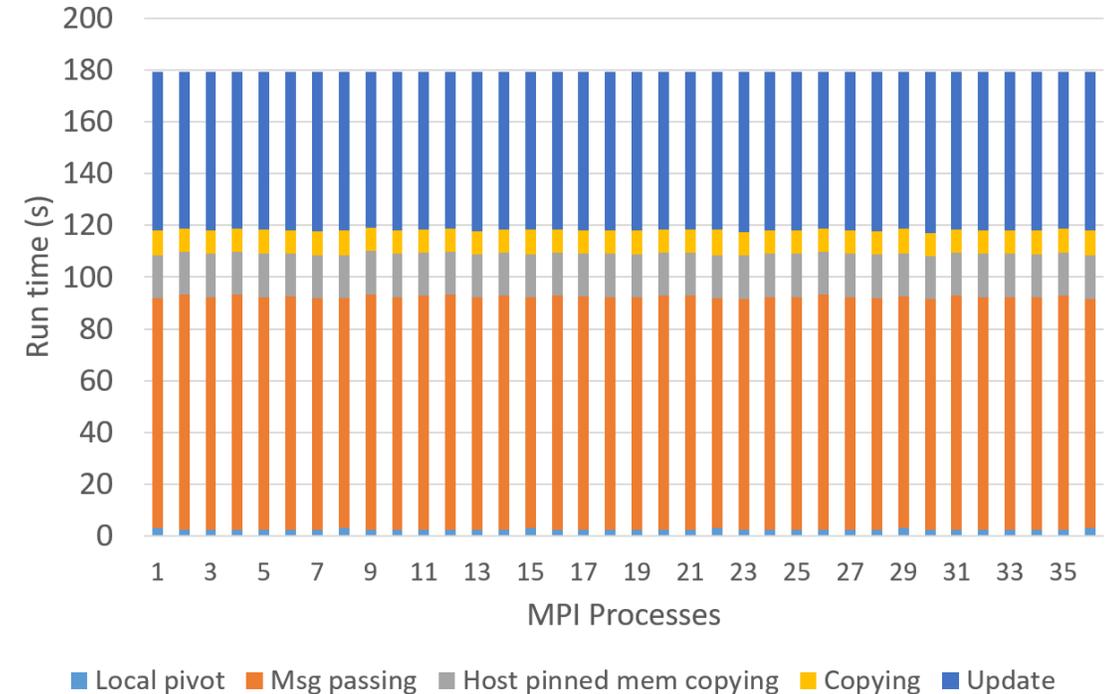

$$N = 27,882$$

Load Balancing Verification

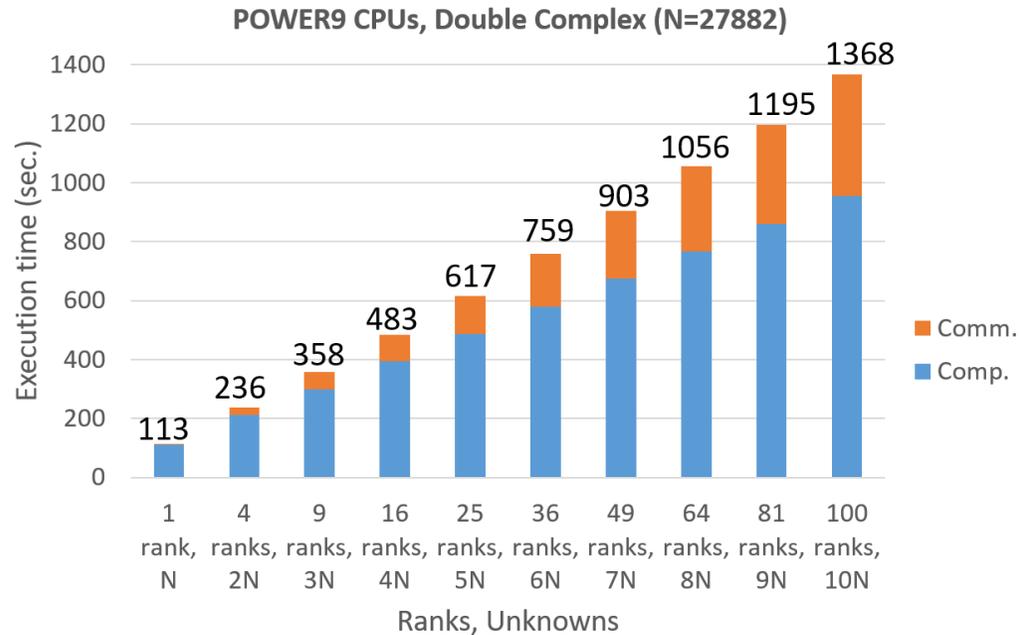

Cuda-aware MPI

- Factorization time on 36 MPI processes (36 GPUs) with the matrix size of $6N \times 6N$ ($167,292 \times 167,292$)
- Communication and update contribute the most to the total time
- Communication time is 1.47x-1.6x the update time

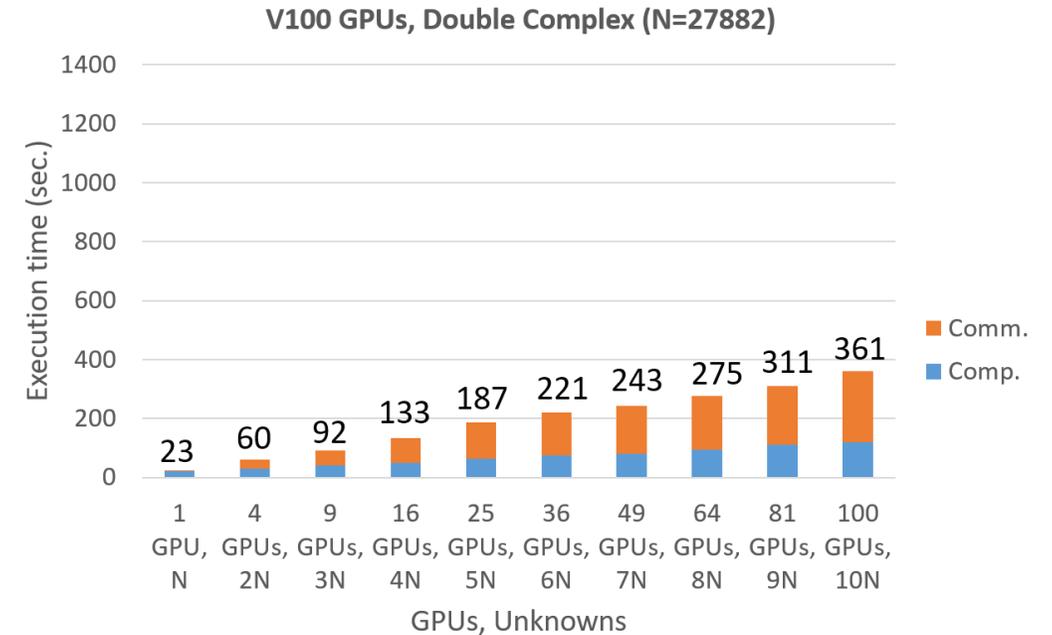

Host pinned memory for MPI

CPU Performance vs. GPU Performance

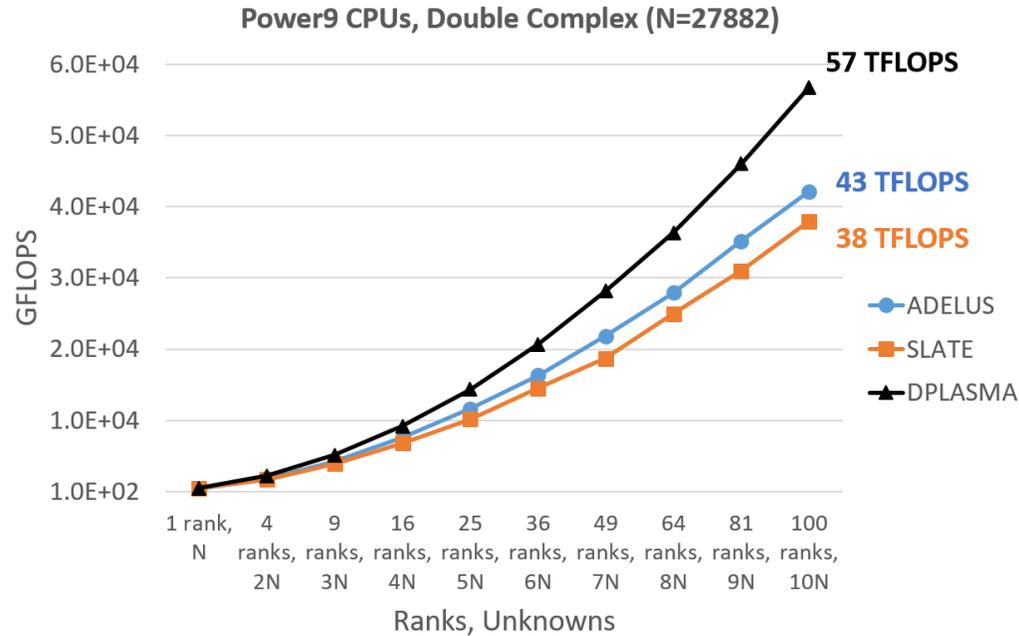

CPU execution time

GPU execution time with host pinned memory

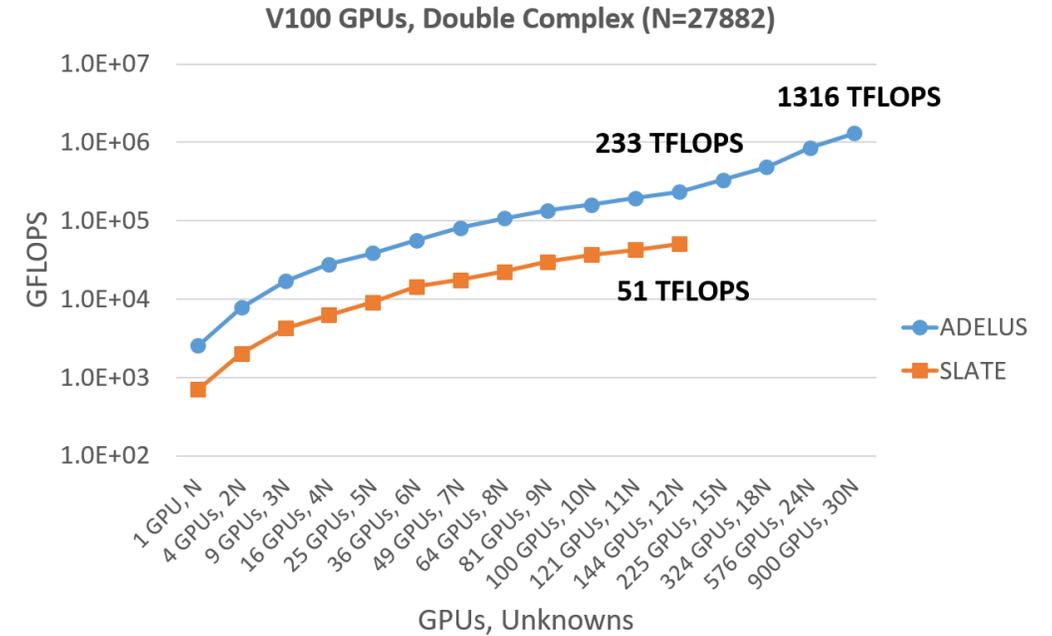

- ❑ A single GPU is **4.9x** faster than a 42-core CPU while 100 GPUs are **3.8x** faster than 100 42-core CPUs
- ❑ Communication overhead increases as processing larger problems (mostly by **broadcasting pivot rows** and **exchanging rhs vectors** among column processes)
- ❑ **CPU computation** is still the dominant component in the total CPU time
- ❑ **GPU computation** is fast that makes **the communication overhead** the bottleneck

ADELUS vs. DPLASMA and SLATE

CPU performance

- ❑ Tuning DPLASMA and SLATE for their best performance
- ❑ ADELUS (43 TFLOPS) outperforms SLATE (38 TFLOPS) while is slower than DPLASMA (57 TFLOPS) on 100 CPUs
- ❑ ADELUS is 4.57x faster than SLATE on 144 GPUs
- ❑ ADELUS can achieve 1.3 PFLOPS with 900 GPUs (the first complex, dense LU solver reaches PFLOPS performance)

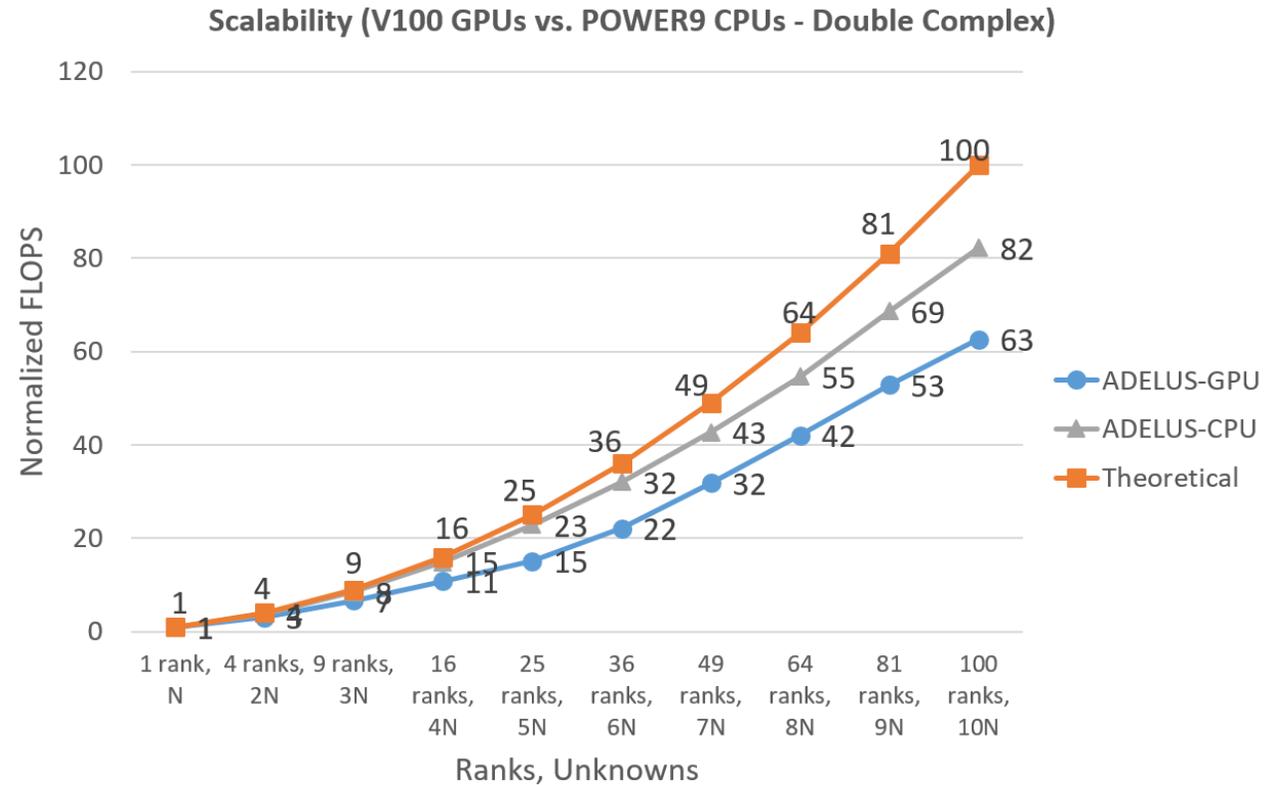

GPU performance

Scalability Analysis

- Scalability is defined as the normalized FLOPS of multiple MPI processes with respect to FLOPS of a single MPI process
- The increase of communication overhead results in below ideal scalability in both CPU and GPU runs
- ADELUS on CPUs scales more closely to the theoretical ideal scalability than ADELUS on GPUs
- GPU performance is **MPI bound** due to the increase in the communication cost and its high FLOPS
- Scalability needs further improvement

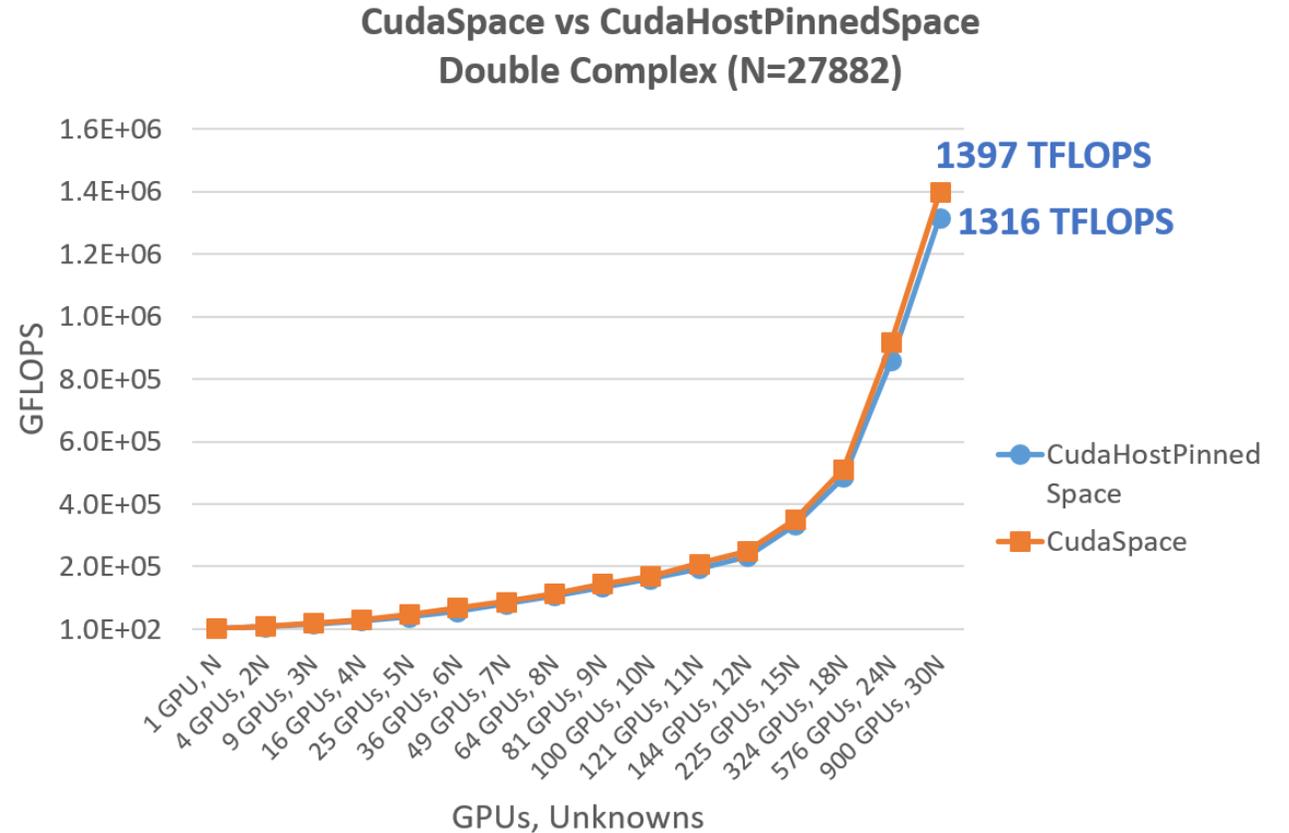

$$S = \frac{\text{FLOPS}(m \text{ ranks/GPUs}, n * N \text{ unknowns})}{\text{FLOPS}(1 \text{ rank/GPU}, 1 * N \text{ unknowns})}$$

where ranks/GPUs = 1, 4, 9, 16, 25, 36, 49, 64, 81, 100
 unknowns = 1N, 2N, 3N, 4N, 5N, 6N, 7N, 8N, 9N, 10N

MPI Buffers on Different Memory Spaces

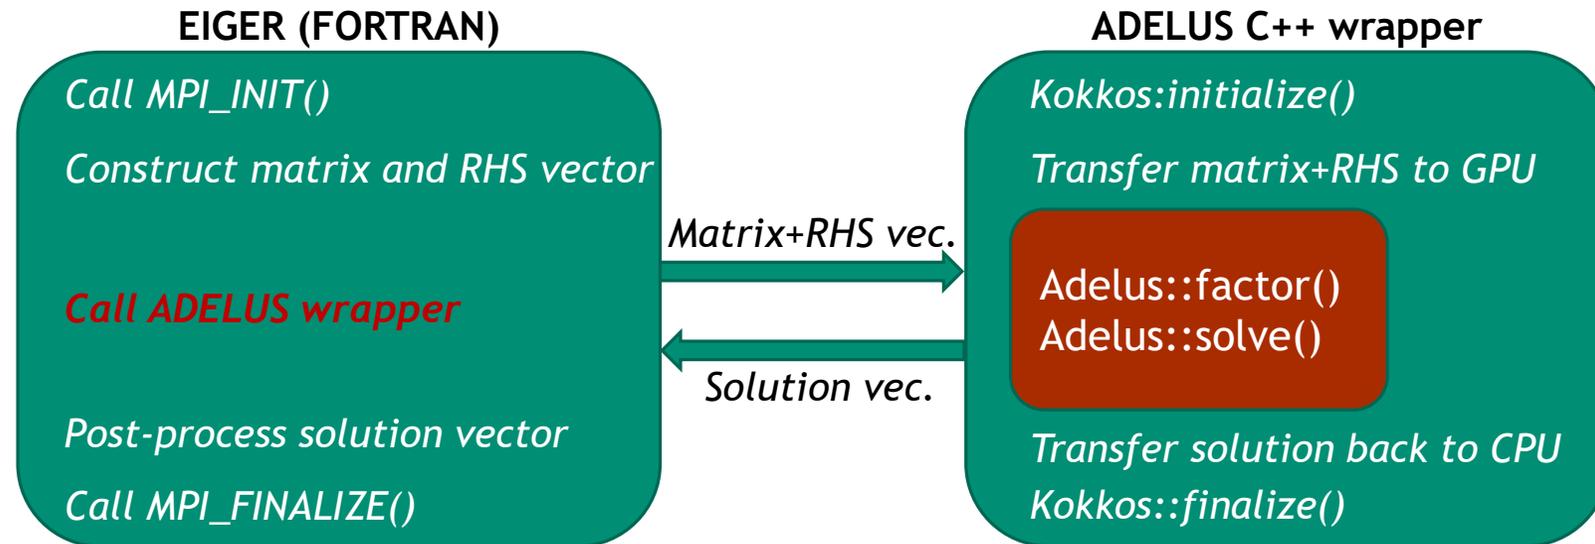

- Both CudaSpace and CudaHostPinnedSpace can attain performance above 1000 TFLOPs
- Using CUDA-aware MPI can improve the performance by 6% since we do not need to explicitly buffer data on host memory before or after calling the MPI function

Large-Scale EM Simulation with EIGER

- ❑ Couple EIGER with ADELUS to perform **large-scale electromagnetic** simulations on the LLNL's Sierra platform
- ❑ First time Petaflops performance with a complex, dense LU solver: **7.72 Petaflops** (16.9% efficiency) when using 7,600 GPUs on 1,900 nodes on a **2,564,487-unknown problem**
- ❑ ADELUS's performance is affected by the distribution of the matrix on the MPI processes
 - Assigning more processes per row yields higher performance

N	Nodes (GPUs)	Solve time (sec.)	TFLOPS	Procs/row
226,647	25 (100)	240.5	1291.0	10
1,065,761	310 (1240)	1905.1	1694.5	31
1,322,920	500 (2,000)	6443.9	958.1	20
1,322,920	500 (2,000)	2300.2	2684.1	50
1,322,920	500 (2,000)	2063.6	2991.9	100
2,002,566	1,200 (4,800)	3544.1	6042.6	100
2,564,487	1,900 (7,600)	5825.2	7720.7	80

- ❑ A parallel, dense, performance-portable, LU solver based on torus-wrap mapping and LU factorization algorithm
- ❑ Obtaining portability through Kokkos and Kokkos Kernels
- ❑ ADELUS's performance on Summit: 1.397 PFLOPS on 900 GPUs
- ❑ The GPU execution is 3.8x faster than the CPU execution
- ❑ ADELUS integrated into an electromagnetic application (EIGER) achieves 7.720 PFLOPS on 7600 GPUs (a problem of 2.5M unknowns) on Sierra
- ❑ Future work:
 - Using computation-communication overlapping to improve ADELUS scalability on GPUs
 - A hybrid implementation where both CPU and GPU resources are fully utilized to overcome the limitation of the GPU memory
